

Texel, August 2015

Research on red knots

In 1998 the shorebird group of the Royal Netherlands Institute for Sea Research (Royal NIOZ) launched a color ring program on red knots *Calidris canutus islandica* and *C. c. canutus*. Since the late eighties the species has been studied by our research group which is based on the island of Texel in the Dutch Waddensea. As of August 2015, 7188 red knots have been captured and provided with color-rings in the Dutch Waddensea, 2753 birds at the Banc d'Arguin in West Africa (Mauritania), 133 in the Waddensea of Schleswig-Holstein (Germany), 408 along the Atlantic coast of France and 21 in southern Portugal. The aim for the coming years is to color-ring approximately 500 red knots annually in the Netherlands and 200 annually in Mauritania. From this year onwards, red knots will also be color-ringed (again) on the mudflats in the vicinity of La Rochelle in southern France.

The color ring combination consist of four color-rings and a flag (a ring with a kind of streamer). There are two color-rings on each lower leg (the tarsus) with the flag in one of eight possible positions (Figure 1). The flag colors that have been used since 1998 are shown in Figure 2 and are (in chronological order): Yellow (Y), Red (R), Green (G), Lime (L) and black (N). Each bird also carries a metal ring, this is not part of the color combination. In most cases the metal ring is on the upper leg (tibia), the flag can also be on the tibia, but never a color-ring!

Since 2011, black flags are used in combination with four color rings. The colors used are black (shorthand N in accordance with international agreements for color ringing), Red (R), Yellow (Y), Green (G) and Pale blue (P). To give an example: a red knot with a green over a yellow color-ring on the left leg, a black flag on the right upper leg and two pale blue rings on the lower leg is quoted as N2GYPP. First, the color and position of the flag is noted and then the color-rings from top to bottom, first for the left leg (of the bird) and then for the right leg.

In the early years of the study color-rings were made of a plastic named Darvic. However, this material is no longer in production, so we are currently using a different material that has the properties of Plexiglas. These rings do not have eternal life and are often shorter than the maximum life of a red knot. This means there are incomplete combinations existing as a result of ring loss and some rings may be strongly faded as a result of ultraviolet light. We would also like to receive observations of birds with incomplete color-ring combinations, so we can get an idea of the amount of ring loss.

Observations of red knots can be sent to shorebirds@nioz.nl describing the color ring combination, the observation date and location. Additional data which we would like to receive are: the type of terrain, the flock size and if possible, the ring density (the number of color-ringed individuals and the total number of observed birds) and the plumage (summer or winter plumage; if possible expressed as a percentage).

Best regards and thank you for your observations on behalf of the NIOZ shorebirds team.
